Q2) red light. $\lambda = 680\,nm$

$n = n' + jn''$

$\varepsilon = n^2$

$\varepsilon = (n')^2 - (n'')^2 + 2j \times n' \times n''$

$\alpha = \left(\frac{4\pi}{\lambda} \times n' \right.$

$k = \left(2\frac{\pi}{\lambda} \right) \times n'$

$Z = \left(\frac{\mu}{\varepsilon} \right)^{0.5}$

$P_{absorbed} = 100 \left[1 - e^{-2\alpha - x)} \right]$

$\alpha \rightarrow$ attenuation coefficient

thickness $= 100\,\mu m$
